[The Ruminant Animal : Digestive Physiology and Nutrition ...](#)

Ruminants are mammals that are able to acquire nutrients from plant-based food by fermenting it in a specialized stomach prior to digestion, principally through microbial actions. The process, which takes place in the front part of the digestive system and therefore is called foregut fermentation, typically requires the fermented ingesta to be regurgitated and chewed again. The process of rechewing the cud to further break down plant matter and stimulate digestion is called rumination. The word

[IN D.C. Church, Ed. The Ruminant Animal, Digestive ...](#)

Ruminant stomachs have four compartments: the rumen, the reticulum, the omasum and the abomasum. Rumen microbes ferment feed and produce volatile fatty acids, which is the cow's main energy source. Rumen microbes also produce B vitamins, vitamin K and amino acids.

Dairy animals (Cows & Buffaloes) are the best converters of plant food into human food in terms of milk. This conversion is possible only by undergoing the process of the digestive system of a ruminant. The digested feed is absorbed in the body & utilized for body growth, maintenance & milk production.

[Chapter 16 - Digestion & Absorption to Feed Flashcards ...](#)

Non-ruminant animals are omnivores or carnivores with a single stomach compartment within the digestive system. Hence, the digestive system of the non-ruminant animals is called monogastric. Some examples of non-ruminant animals are human, horse, swine, fowl, dog, and rabbit.

[Ruminant - Wikipedia](#)

C. Classifying animals based on their digestive physiology? 1) Nonruminant animals. a) Pigs - Nonruminant animals that are omnivorous, thus consume both plant and ... Ruminant animals. a) Capable to consume and digest plant materials and classified as herbivores. b) Include cattle, sheep, goats, deer, elk, and many other wild species. ...

[The Ruminant Animal: Digestive Physiology and Nutrition: D ...](#)

Ruminants are hooved mammals that have a unique digestive system that allows them to better use energy from fibrous plant material than other herbivores. Unlike monogastrics such as swine and poultry, ruminants have a digestive system designed to ferment feedstuffs and provide precursors for energy for the animal to use.

[Digestive Systems of Livestock: Anatomy](#)

At the mouth the large food molecules are taken into the gut - this is called ingestion. They must then be broken down into smaller ones by digestive enzymes - digestion, before they can be taken from the gut into the blood stream - absorption. The cells of the body can then use these small molecules - assimilation.

[The ruminant digestive system - University of Minnesota](#)

The cow is a ruminant with four stomachs: rumen; reticulum; omasum; and; abomasum. The Rumen. The rumen is the largest, with a volume of 150-200 litres (40-50 gallons). In the digestion system there are billions of microorganisms. They help the cow to digest and utilize nutrients in the feed.
